Blankophor P was used in a dominant lethal study to test for mutagenic effects in an acute oral study on female mice.

When the applications were begun the females were in the pro-estrous phase; this information was deduced by doing vaginal smears beforehand.

Through these study propositions (protocols) it was evident that Blankkophor P could react on the pre-ovulatory or oocytes status which is the most sensitive status for mutabenic influences.

Two separate experiments were performed; in the first experiment we used doses of 1000 mg/kg and 5000 mg/kg and in the second experiment we used doses of 100 mg/kg, 300 mg/kg and 1000 mg/kg. Control groups received an adequate volume of the solvent which was 20 ml/kg water administered orally. The study groups included 35-42 female mice which were immediately paired with nontreated males.

Examination of the fertilized females occured on the 14th day of pregnancy. The preimplanted and post implanted loses, which were the test criteria for induced lethal mutation, were investigated through the number of corpea lutea and the implantation sites for the living and dead fetuses. The results were statistically correlated.

Blankophor P was tolerated in doses up to 5000 mg/kg orally in females without any noticable influences on their behavior.

Blankophor P did not influence, as seen when compared to control animals in doses up to 300 mg/kg bodyweight orally, the pre or post implanted fetus loses. Therefore, in this dose range there was no evidence of a mutagenic effect.

Dosis of 1000 and 5000 mg/kg orally produced dose dependent dominant lethal effects which was evident in increased mortality of the fetuses before implantation. Post implanted losses were not increased up to doses of 5000 mg/kg orally.

Female mice seemed thereafter to be more sensitive than male mice where 1000 mg/kg Blankophor P per kg bodyweight orally showed no effect in the dominant lethal test. However, the 5000 mg/kg oral dose also produced lethal effects in male mice.

BAYER AG INSTITUT FÜR TOXIKOLOGIE Wt.-Elberfeld, 9.12.1974

Bericht Nr.:

Exemplar Nr.:

# UNTERSUCHUNG VON BLANKOPHOR P AUF MUTAGENE WIRKUNG AN DER MAUS

(Dominant-Letal-Test bei Behandlung der weiblichen Tiere)

von

L. Machemer

Solange die in dieser Arbeit enthaltenen Ergebnisse nicht publiziert worden sind, dürfen sie nur mit Einverständnis der BAYER AG - Institut für Toxikologie - verwendet werden. Eine weitere Verfielfältigung dieses Berichtes - auch auszugsweise - ist nicht gestattet.

### **ZUSAMMENFASSUNG**

Es wurden mit Blankophor P (Natriumsalz) Dominant-Letal-Versuche zur Prüfung auf mutagene Wirkung bei akuter oraler Behandlung weiblicher Mäuse durchgeführt. Zum Zeitpunkt der Applikation beganden sich die Weibchen in der Pro-Oestrusphase, dies wurde zuvor durch Untersuchung von Vaginalabstrichen ermittelt. Hiermit waren die Voraussetzungen gegeben, daß Blankophor P auf die für mutagene Einflüsse am empfindlichsten reagierenden, praeovulatorischen Oocytenstadien einwirken konnte.

Es wurden 2 unabhängige Experimente durchgeführt, im ersten wurden Dosen von 1 g/kg und 5 g/kg im zweiten wurden Dosen von 0,1 g/kg, 0,3 g/kg und 1 g/kg untersucht. Kontrollen erhielten das adaequate Volumen des Lösungsmittels, d.h. 20 ml/kg Wasser per os. Die Versuchsgruppen umfaßten je 35-42 weibliche Mäuse, die unmittelbar nach der Applikation mit unbehandelten Männchen verpaart wurden.

Die Untersuchung der besamten Weibchen erfolgte am 14. Tag der Trächtigkeit, wobei die praeimplantativen und die postimplantativen Verluste, die in diesem Test die Kriterien für induzierte Letalmutationen darstellen, anhand der Zahl der Corpora lutea, der Implantationen und der lebenden und toten Keimlinge ermittelt wurden. Die Ergebnisse wurden statistisch ausgewertet.

Blankophor P wurde in Dosen bis 5 g/kg Körpergewicht p.o. von den Weibchen ohne erkennbare Beeinträchtigung toleriert.

Blankophor P beeinflußte - wie der Vergleich mit den Ergebnissen der Kontrolle zeigte - in Dosen bis 0,3 g/kg Körpergewicht p.o. nicht nachweislich die praeimplantativen und die postimplantativen Keimverluste, so daß sich kein Anhaltspunkt für eine mutagene Wirkung in diesem Dosisbereich ergab.

Dosen von 1 g/kg und 5 g/kg p.o. erzeugten dosisabhängig Dominant-Letal-Effekte, die sich in einem vermehrten Absterben der Keimlinge vor der Implantation äußerte. Die postimplantativen Verluste wurden durch Dosen bis 5 g/kg p.o. nicht nachweislich gesteigert.

Weibliche Mäuse schienen demnach empfindlicher zu reagieren als männliche Mäuse, bei denen 1 g/kg Blankophor P pro kg Körpergewicht p.o. im Dominant-Letal-Test eine no-effect-Dosis war; die Dosis 5 g/kg p.o. erzeugte aber auch bei männlichen Mäusen Letaleffekte.

### EINLEITUNG

Dominant-Letal-Untersuchungen an männlichen Mäusen hatten ergebel, daß 5 g Blankophor P pro kg Körpergewicht, einmalig per os gegeben, einen schwachen mutagenen Effekt in postmeiotischen Spermatogenesestadien ausüben kann; die Dosis 1 g/kg per os war in dieser Hinsicht eine no-effect-Dosis (1).

Zytogenetische Untersuchungen an Spermatogonien von Chinesischen Hamstern, die 2 x 5 g Blankophor P pro kg Körpergewicht per os im Abstand von 24 Stunden erhalten hatten, erbrachten keinen Hinweis auf einen mutagenen Effekt im Sinne der Erzeugung struktureller Chromosomenveränderungen (2).

Die nachfolgend dargestellen Dominant-Letal-Untersuchungen mit Blankophor P-Behandlung von weiblichen Mäusen sollten zeigen, ob der bei männlichen Mäusen gefundene mutagene Effekt auch bei weiblichen Mäusen nachzuweisen ist. Die Verwendung von weiblichen Mäusen im Dominant-Letal-Test hat den Vorteil, daß die Oocyten keiner Selektion und Elimination mehr vor der Befruchtung unterliegen, sobald sie in die für mutagene Einwirkungen besonders sensitiven praeovulatorischen Meioseschritte eingetreten sind. Oocyten erscheinen daher geeignet, die in dieser kritische Phase eintretenden Mutationen unmittelbar und uneingeschränkt erfassbar zu machen.

In Untersuchungen mit mutagen wirkenden Alkylantien an verschiedenen Mäusestämmen haben wir gefunden, daß die Behandlung von Weibchen im Pro-Oestrus gut geeignet ist, um dominant Letalmutationen zu erzeugen (3, 4). Daher führten wir die nachfolgend dargestellte Untersuchung mit Blankophor P bei Verabreichung an pro-oestrische Mäuseweibchen durch.

### <u>methoden</u>

### 1. Substanz

Blankophor P, Natriumsalz, Probe vom 6.7.1972 (Dr. Schminke, W-N 14). Es handelt sich um einen optischen Aufheller für die Papierindustrie.

Konstitution:

# 2. Tiere und Versuchsdurchführung

Es wurden Mäuse des Stammes NMRI (Züchter und Lieferant: S.IVANOVAS GmbH, Kisslegg/Allgäu) verwendet. Die Tiere waren zu Versuchsbeginn 10 - 12 Wochen alt und wogen 20 - 25 g (Weibchen) bzw. 30 - 35 g (Männchen).

# 1. Experiment:

42 weibliche Mäuse pro Gruppe erhielten im Pro-Oestrus einmalig 1 g oder 5 g Blankophor P pro kg Körpergewicht per os in 20 ml entmineralisiertem Wasser pro kg Körpergewicht mit der Schlundsonde. Die Brunstphasen wurden zuvor durch Untersuchung von Vaginalabstrichen bestimmt.

Eine Kontrollgruppe von 41 Weibchen bekam nur entmineralisiertes Wasser, 20 ml/kg einmalig per os, im Pro-Oestrus.

# 2. Experiment:

35 - 40 weibliche Mäuse pro Gruppe erhielten im Pro-Oestrus einmalig 0,1, 0,3 oder 1 g Blankophor P pro kg Köspergewicht per os in 20 ml entmineralisiertem Wasser pro kg Köspergewicht mit der Schlundsonde. Eine Kontrollgruppe von 41 Weibchen bekam nur entmineralisiertes Wasser, 20 mg/kg einmalig per os, im Pro-Oestrus.

Unmittelbar nach der Applikation wurden je 2 behandelte Weibchen über Nacht mit einem unbehandelten Männchen verpaart. 16 Stunden später wurden die Weibchen auf das Vorhandensein eines Vaginalpfropfes als Zeichen stattgefundener Besamung untersucht. Nur besamte Weibchen wurden für die späteren Untersuchungen verwender.

Am 14. Tag der Trächtigkeit erfolgte die Untersuchung der Weibchen zur Erwittlung der prae- und postimplantativen Keimverluste, der Kriterien für die Beurteilung induzierter Letalmutationen. Hierzu wurden die Corpora lutea, die Implantationen, die lebenden Keimlinge und die toten Implantate (Summe der Deziduomata = "leere" Implantationsstellen, der Resorptionen sowie der toten Keimlinge) gezählt.

# 3. Haltungsbedingungen der Versuchstiere

Mit Ausnahme der nächtlichen Verpaarung saßen die Versuchstiere einzeln in Makrolonkäfigen vom Typ I. Die Haltangsbedingungen waren konventionell bei täglich 12 Stunden elektrischem Licht. Die Raumtemperatur betrug 24-26°C, und die durchschnittliche, relative Luftfeuchtigkeit war ca. 60%. Die Tiere erhielten pelletiertes Altromin®-Futter und Wasser ad libitum.

# 4. Statistik

Die Reproduktionsparameter wurden statistisch ausgewertet.

Die Anzahlen der Corpora lutea, der Implantationen und der
lebenden Keimlinge der Weibchen der unbehandelten und der
behandelten Gruppen wurden mit dem t-Test verglichen. Waren
die Voraussetzungen für den t-Test nicht erfüllt, so wendeten

wir den verteilungsfreien Rangsummentest nach WILCOXON (5) an. Unterschiede der Befruchtungsrate und der Anzahlen der toten Implantate beider Versuchsgruppen wurden mit dem chi<sup>2</sup>-Test statistisch geprüft.

Differenzen galten als statistisch signifikant, wenn die Irrtumswahrscheinlichkeit, daß diese Differenzen zufällig waren, kleiner als 5% war (p < 0,05).

### **ERGEBNISSE**

Die Ergebnisse wurden in der Tabelle 1 zusammengestellt, sie geben über folgende Parameter Aufschluss:

- Befruchtungsquote (%)
  - = Anzahl befruchtete Webchen x 100 Anzahl eingesetzte Weibchen
- Ovulationsrate
  - = Corpora lutea pro Weibchen
- Implantationsrate
  - = Implantationen pro Weibchen
- Praeimplantativer Verlust
  - = Anzahl Corpora lutea minus Anzahl Implantationen (pro Weibchen und in % der Corpora lutea)
- Lebende Embryonen pro Weibchen
- Postimplantativer Verlust
  - = Summe der Deziduomata, der Resorptionen und der toten Embryonen (pro Weibchen und in % der Implantationen)

Aus der Tabelle 1 ist zu ersehen, daß die Behandlung der Weibchen mit Blankophor P in Dosen bis 5 g/kg per os, die symptomlos toleriert wurden, keinen Einfluß auf die Befruchtungsquote hatte.

Dagegen ist erkennbar, daß der Praeimplantationsverlust (= der vor der Implantation eintretende Verlust von Keimlingen) durch die Dosen 1 g/kg und 5 g/kg in dosisabhängiger Weise und gegenüber der Kontrolle signifikant gesteigert wurde.

Als Folge davon waren im 1. Experiment die Anzahlen der Implantationen und der lebenden Embryonen pro Weibchen gegenüber der Kontrolle deutlich vermindert, im Falle der hohen Dosis, 5 g/kg, war dies statistisch signifikant. Im 2. Experiment waren in der 1 g/kg-Gruppe (höchste Dosis in diesem Experiment) trotz des erhöhten Præeimplantationsverlustes die Anzahlen der Implantationen und der lebenden Embryonen gegenüber der Kontrolle nicht vermindert; sie lagen sogar höher als die Kontrollwerte, da die 1 g/kg-Gruppe eine besonders hohe durchschnittliche Anzahl von Corpora lutea aufwies. Bis zur Dosis 0,3 g/kg war keinerlei Wirkung auf den Præeimplantationsverlust erkennbar.

Der <u>postimplantative</u> Verlust wurde durch die Blankophor P-Behandlung der Weibchen mit Dosen bis 5 g/kg p.o. nicht nachweislich erhöht. Dies gilt trotz der statistisch signifikant höheren Rate der Totimplantate der 5 g/kg-Gruppe. Denn diese Signifikanz wurde durch ein einzelnes Tier (von 36 befruchteten Tieren) verursacht, dessen Keimlinge alle abgestorben waren. Vollständiger Keimverlust kommt jedoch bei Mäusen nicht selten vor, so daß dieser Einzelbefund höchstwahrscheinlich nicht mit der Behandlung in Zusammenhang stand. Wenn man dieses eine Tier nicht berücksichtigte, sondern nur die übrigen 35 Tiere dieser Gruppe, so zeigte die Rate der Totimplantate keinen Einfluß der Behandlung an.

### BEURTEILUNG

Aus den Ergebnissen von Dominant-Letal-Versuchen an weiblichen Mäusen mit Blankophor P ergab sich kein Hinweis, daß die einmalige orale Verabreichung im Pro-Oestrus von Dosen bis 0,3 g/kg mutagene Effekte zur Folge hatte: Der praeimplantative und der postimplantative Keimverlust blieben unbeeinflußt im Vergleich zur Kontrolle.

Die Verabreichung im Pro-Oestrus fiel mit dem Ablauf der praeovulatorischen Meioseschritte der für die Befruchtung dienenden Oocyten zusammen und bot somit die Voraussetzung für ein Einwirken von Blankophor P auf sensitive Oocytenstadien. Denn die Oocyten der Maus durchlaufen vom Zeitpunkt der frühesten Bereitschaft zur Kopulation, die im Pro-Oestrus zu beobachten ist, bis zur Ovulation die Stadien Prometaphase I bis Metaphase II (6). Diese Stadien haben sich als die empfindlichs en erwiesen für mutagene Einwirkungen von Alkylantien (7) und Röntgenstrahlen (8).

Dosen ab 1 g/kg per os erzeugten in dosisabhängiger Weise dominante Letaleffekte, die sich in einem vermehrten Absterben von Keimlingen vor der Implantation äußerten.

Blankophor P erzeugte somit im Dominant-Letal-Test sowohl bei männlichen als auch bei weiblichen Mäusen Letaleffekte, wobei die weiblichen Mäuse empfindlicher zu sein schienen. Denn ein Effekt trat hier ab der Dosis 1 g/kg auf, diese Dosis war bei männlichen Mäusen eine no-effect-Dosis im Hinblick auf dominante Letalwirkung (1).

Nachweiß auf dominante Letalmutationen nach einmaliger, oraler Behandlung weibl. Mäuse im Proöstrus mit Blankophor P ( 2. Versuch )

Tiermaterial

: je Gruppe 7 Männchen, Stamm NMRI Züchter Ivanovas, beim Einsetzen im Gewicht zwichen
30 - 35 g
Weibchen im Proöstrus, gleicher Stamm und
Züchter.

Substanz

: Blankophor P
von Dr.Schminke (6. 7. 72) W-N 14

Dosen

: 100 mg/kg 300 mg/kg 1000 mg/kg

Verabreichung

: Die Substanz wurde oral mit einem Applikationsvolumen von 20 ml/kg verabreicht. Lösungsmittel war Levatitwasser.

Verhalten d. Tiere

: Die Weibchen vertrugen die Behandlung mit Blankophor P ohne erkennbare äußerliche Beeinträchtigung.

Mortalitat

: Durch die Behandung mit Blankophor P starb während des Versuches kein Tier .

Befruchtungsquote

: Die Befruchtungsquoten lagen zwischen 26,5 % ( 1000 mg/kg ) und 94,3 % ( 300 mg/kg ). Kein Ergebniss lag signifikant unterschiedlich zur Kontrolle. Alle Ergebnisse lagen im Normalbereich.

Präimplantativer Verlust Der praeimplantative Verlust der Behandlungsgruppe 1000 mg/kg beträgt 0,8 pro Weibchen und ist damit signifikant (5% ige IW) schlechter als der ermittelte Kontrollwert.(0,4 pro Weibchen). Die Anzahl der Implantate pro Weibchen liegt bei dieser Behandlungsgruppe jedoch noch 0,9 Implantate pro Weibchen höher als der Kontrollwert. Ein Effekt kann deshalb nicht als wahrscheinlich angesehen werden.

In einem früheren Versuch mit Blankophor P wurde bei gleicher Dosis ein praeimplantativer Verlust (0,9/Weebchen, Kontrolle 0,4) bei

### **ZUSAMMENFASSUNG**

Blankophor P wurde in Dominant-Letal-Untersuchungen an männlichen NMRI-Mäusen, die auf chemische Mutagene empfindlich reagieren, nach oraler Verabreichung auf mutagene Effekte geprüft.

Es wurden 3 unabhängige Untersuchungen durchgeführt, deren Versuchsgruppen je 20 männliche und 60 weibliche Tiere pro Paarungswoche umfaßten. Zu jeder Untersuchung gehörte eine unbehandelte Kontrollgruppe.

Die männlichen Mäuse wurden wie folgt behandelt:

- 1. Versuch Untersuchung über 8 Paarungswochen: Einmalige Gabe von 5 g/kg Körpergewicht per os
- 2. Versuch Wiederholungs-Untersuchung über 8 Paarungswochen Einmalige Gabe von 5 g/kg Körpergewicht per os
- 3. Versuch Untersuchung über 3 Paarungswochen: Einmalige Gabe von 1 g/kg und 5 g/kg Körpergewicht per os.

Nach der Applikation wurden die Männchen mit je 3 unbehandelten Weibchen gepaart. Zur Untersuchung der aufeinanderfolgenden Keimzellstadien der Männchen wurden jede Woche 3 neue, unbehandelte Weibchen zu jedem Bock gesetzt zur Besamung.

Die Untersuchung der Weibchen erfolgte um den 14. Tag der Trächtigkeit.

Felgende Parameter wurden erfaßt: Allgemeine Verträglichkeit der Behandlung, Befruchtungsfähigkeit der Männchen, praeimplantativer Verlust und postimplantativer Verlust, wobei die Zahl der Corpora lutea, der Implantationen, der lebenden und der toten Keimlinge ermittelt wurden. Die biometrische Auswertung erfolgte für bezogene Größen varianzanalytisch mit entsprechenden Transformationen und für Verteilungsvergleiche der Zielgrößen mittels des Kolmogorov-Smirnov-Tests.

Die wesentlichen Ergebnisse der Dominant-Letal-Untersuchungen mit Blankophor P waren: In den 3 unabhängigen Untersuchungen fanden sich Hinweise, daß 5 g/kg KG p.o. in postmeiotischen Spermatogenesestadien dominante Letalfaktoren induzierte, kenntlich an einer Zunahme der postimplantativen Verluste im Vergleich zur Kontrolle in einzelnen Paarungswochen. Die Effekte waren zwar nur im 1. Experiment statistisch signifikant bzw. im 2. Experiment fast signifikant, aber die gleichartigen, wenn auch geringen Effekte in allen Untersuchungen sprachen für einen Substanzeffekt.

Eine zusätzlich durchgeführte Prüfung von 1 g Blankophor P pro kg KG p.o. während der kritischen, postmeiotischen Phase (1.-3. Paarungswoche nach Applikation) ergab keinen Hinweis auf mutagene Effekte.

Die Befruchtungsquoten und der praeimplantative Verlust, die allerdings für die Beurteilung einer mutagenen Wirkung wenige bedeutsam sind als der postimplantative Verlust, ließen allgemein nicht auf nachteilige Substanzeffekte in Dosen bis 5 g/kg KG p.o. schließen. Waren statistische Signifikanzen, wie z.B. im Falle der Befruchtungsquoten vorhanden, so waren diese als zufällig anzusehen.

Dominant-Letal-Untersuchungen mit Blankophor P an männlichen Mäusen haben Anhaltspunkte für eine mutagene Wirkung der aküten oralen Dosis von 5 g/kg KG ergeben.

Die akute Dosis von 1 g/kg KG p.o. war in der entsprechenden Versuchsanordnung eine no-effect-Dosis.

### 1. EINLEITUNG

Mit dem Dominant-Letal-Test lassen sich künstlich erzeugte Mutationen ("Letalfaktoren") nachweisen. Es sind dies die in befruchtungsfähigen Keimzellen induzierten Chromosomenund dominanten Gen-Mutationen, die zu einem frühen Absterben der betroffenen Zygoten führen (1, 2). Sie lassen sich durch Uteruspräparation in einem fortgeschrittenen Gestationsstadium als "postimplantativer Verlust" (nach der Implantation abgestorbene Keimlinge) oder als "praeimplantativer Verlust" (vor der Implantation abgestorbene Eier und Blastocysten) erfassen.

Ist die Letalrate in der behandelten Gruppe nachweisbar größer als in der Kontrollgruppe, die stets eine bestimmte stammesspezifische Letalrate aufweist, so ist unter bestimmten Voraussetzungen auf induzierte Mutationen zu schließen.

Dieser Test, der vorzugsweise an Mäusen durchgeführt wird, hat folgende Vorteile:

- 1. Er erlaubt den Nachweis von Mutationen in Keimzellen.
- 2. Er wird an einem Säuger in vivo durchgeführt, wodurch Stoffwechsel und Kinetik beim lebenden Organismus berücksichtigt werden, und der Applikationsweg entsprechend der zu beurteilenden Gefährdung des Menschen gewählt werden kann.

In dem vorliegenden Bericht werden Untersuchungen von Blankophor P auf mutagene Wirkungen im Dominant-Letal-Test nach akuter oraler Behandlung männlicher Mäuse beschrieben.

### 2. METHODEN

### 2.1. Substanz

Blankophor P, Natriumsalz, 6.7.72 Dr. Schminke, W-N14

### 2.2. Tiere und Haltungsbedingungen

Mäuse des Stammes NMRI. Züchter und Lieferant S. Ivanovas GmbH, Kisslegg/Allgäu. Das Gewicht der Männchen betrug zu Versuchsbeginn 30 - 35 g, das Gewicht der Weibchen lag zwischen 25 und 30 g. Das Alter der Tiere war ca. 10 Wochen. 20 männliche und 60 weibliche Mäuse pro Cruppe pro Paarungswoche.

Haltung in Makrolonkäfigen, Typ I:

- a) während der nächtlichen Verpaarung je 1 Männchen mit 3 zu besamenden Weibchen, tagsüber Einzelhaltung der Männchen,
- b) während der Gestation Einzelhaltung der Weibchen.

Konventionelle Haltungsbedingungen bei täglich 12-stündige elektrischem Licht, 24 - 26°C Raumtemperatur und ca. 60% durchschnittlicher relativer Luftfeuchtigkeit.

Futter (Altronin®, pelletiert) und Leitungswasser ad libitum.

# 2.3. Applikation von Blankophor P

AMre Weibchen in diesen Untersuchungen blieben unbehandel:

- Den männlichen Mäusen wurde einmalig folgende Dosen per o:

- mit der Schlundsonde verabreicht:

	g/kg	Konzentration (%)
1. Versuch		
Kontrolle	0	-
Dosis	5	20
2. Versuch		
Kontrolle	0	<u>-</u>
Dosis	5	20
3. Versuch		4
Kontrolle	0	\ <u>\</u>
1. Dosis	1	<b>⋄</b> 4
2. Dosis	5	20

Blankophor P war in allen Experimenten in entmineralisiertem Wasser mit 0,5% Cremophor gelöst. Volumen 25 ml/kg Körpergewicht in allen Gruppen.

Die Männchen der Kontrollgruppen erhielten einmalig das adaeqaute Volumen entmineralisiertes Wasser mit 0,5% Cremophor.

# 2.4. Paarung

Beginnend am Tage der Applikation wurden mit den Böcken Paarungsperioden von je einer Woche Dauer durchgeführt, wobei jede Woche 3 neue, unbehandelte Weibchen zu jedem Bock gesetzt wurden (1. und 2. Versuch: 8 Paarungswochen, 3. Versuch: 3 Paarungswochen).

Die Verpaarung der Männchen und Weibchen erfolgte stets nur während der Nachtstunden, bei Tagesbeginn wurden die Weibchen auf das Vorhandensein eines Vaginalpfropfens untersucht. Diese Methode ist gut geeignet zur Erzielung reproduzierbarer Ergebnisse (3).

Besamte Weibchen wurden von dem Männchen getrennt. Weibchen bei denen kein Vaginalpfropf gefunden worden war, wurden nach einer Woche ebenfalls einzeln gesetzt.

### 2.5. Untersuchung der Weibchen

Um den 14. Tag der Trächtigkeit oder 14 Tage nach Trennung von dem Männchen erfolgte die Uterusuntersuchung zur Ermittlung der prae- und postimplantativen Verluste, der Kriterien für die Beurteilung. Hierzu wurden die Corpora lutea, die Implantationen, die lebenden Keimlinge und die toten Implantate (Summe der Deziduomata = "leere" Implantationsstellen, der Resorptionen und der toten Embryonen) gezählt.

### 2.6. Biometrie

Die biometrische Auswertung erfolgte durch die Abteilung Dokumentation und Biometrie, Ressort Pharma-Entwicklung der BAYER AG.

Die Anzahlen der toten Implantate und aller Implantate (wurzeltransformiert) die Befruchtungsquote (winkeltransformiert), sowie das Verhältnis der Totimplantate zu den Gesamtimplan aten (winkeltransformiert) wurden mit der 2-faktoriellen Varianzanalyse geprüft. Für den Fall, daß der F-Test für die Faktoren Dosis bzw. Zeit signifikant (p < 0,05) war, wurde die Grenzdifferenz nach dem TUKEY-Test angegeben.

Die Kontraste zwischen den Prüfgliedern (Kontrolle, Dosis) sowie die Änderungen in der Zeit wurden mit der Methode der orthogonalen Vergleiche untersucht. Die in den Varianzanalysen bei der Zerlegung des Faktors Behandlungsgruppen angegebenen Kontraste sind folgendermaßen zu verstehen:

Ferner wurden mit dem verteilungsfreien <u>KOLMOGOROV-SMIRNOV-Test die Häufigkeitsverteilungen</u> einzelner Parameter (tote Implantate, Implantate, lebende Implantate, praeimplantativer Verlust) in Kontrolle und Behandlungsgruppe verglichen.

- / -

### 3. ERGEBNISSE

Die Auflistung der Einzelergebnisse aller verpaarten Weibchen findet sich im Anhang 1-22 zu diesem Bericht.

### 3.1. Allgemeine Verträglichkeit für die männlichen Mäuse

Nach der Applikation zeigten die in den verschiedenen Experimenten mit Dosen bis 5 g/kg KG behandelten männlichen Mäuse keine spezifischen Schädigungssymptome. Die Tiere hatten lediglich bis zu 3 Tagen nach der Applikation gelb-grün verfärbten Kot, bedingt durch die Ausscheidung unveränderten Blankophors P. Alle behandelten Männchen überlebten bis zum Versuchsende.

# 3.2. <u>Dominant-Letal-Untersuchungen</u>

Es wurden folgende Hauptparameter ermittelt:

Befruchtungsquote: Darunter ist folgender Prozentsatz zu verstehen

Anzahl der befruchteten Weibchen x 100
Anzahlb der eingesetzten Weibchen

<u>Postimplantativer Verlust:</u> Er stellt das wichtigste Kriterium für die Beurteilung einer mutagenen Wirkung in diesem Testmodeld dar. Er ergibt sich aus der

Summe der Deziduomata

der resorbierten Keimanlagen und
der toten Keimlinge.

Praeimplantativer Verlust: Er ist die Differenz

Anzahl der Corpora lutea minus

Anzahl der Implantationen.

Er kann auch indirekt abgeschätzt werden durch einen Vergleich der durchschnittlichen Implantationszahlen pro befruchtetes Weibchen in der unbehandelten und der behandelten Gruppe.

Da die Implantationen im Gegensatz zu den Corpora lutea exakt zu zählen sind, gelangt die indirekte Abschätzung der praeimplantativen Verluste anhand der Implantationszahlen letztlich zu schlüssigeren Aussagen als die direkte auf der Basis der Corpora lutea-Zählung.

# 3.2.1. Befruchtungsquote

Die Befruchtungsquoten der 3 unabhängigen Untersuchungen mit Blankophor P wurden in den Tabellen 1 (1. Versuch), 2 (2. Versuch) und 3 (3. Versuch) angegebén.

Die varianzanalytischen Auswertungen der Daten (Tabelle 10 = 1. Versuch, Tabelle 11 = 2. Versuch, Tabelle 12 = 3. Versuch) ergaben:

Die mit 5 g/kg KG p.o. behandelte Gruppe im 1. Versuch wies eine signifikant niedrigere Befruchtungsquote als die Kontrolle auf, dies war vor allem durch die Ergebnisse ab der 2. Paarungswoche bedingt. Außerdem wurde ein signifikanter Zeiteinfluß festgestellt. Er bestand darin, daß die Befruchtungsquoten im Verlaufe der Untersuchung abnahm; dieser Effekt war in Kontrolle und Blankophor P-Gruppe gleichermaßen festzustellen.

Im 2. Versuch Spit 5 g/kg KG p.o. hatte die Kontrollgruppe eine signifikant niedrigere Befruchtungsquote als die Blankophor P-Gruppe. Ein signifikanter Zeiteinfluß war nicht festzustellen.

Im 3. Versuch, bei Gabe von 1 g/kg und 5 g/kg KG p.o., unterschieden sich die Befruchtungsquoten der Kontrolle und der 5 g/kg-Gruppe nicht bedeutsam. Hingegen hatte die 1 g/kg-Gruppe eine signifikant größere Befruchtungsquote als die Kontrolle. Ein signifikanter Zeitfaktor war nicht vorhanden.

Aus den Ergebnissen der 3 Untersuchungen ist keine Gesetzmäßigkeit erkennbar, die auf einen Einfluß der Blankophor P-Behandlung der männlichen Mäuse auf das Befruchtungsergebnis schließen ließe. Die festgestellten statistischen Signifikanzen waren widersprüchlich und müssen als zufälli angesehen werden.

3.2.2. Die in den 3 Untersuchungen mit Blankophor P ermittelten <u>postimplantativen Verluste</u> wurden in den Tabellen 4 (1. Versuch), 6 (2. Versuch) und 8 (3. Versuch) zusammengestellt.

Die statistische Bearbeitung der Daten (Varianzanalysen und Kolmogorov-Smirnov-Tests) ist in den Tabellen 13 - 24 dargelegt.

Im Einzelnen ergibt sich daraus:

Im 1. Versuch mit 5 g/kg KG p.o. ergaben sich in der 2. und 3. Paarungswoche relativ hohe durchschnitt-liche postimplantative Verluste im VergYeich zur Kontrolle.

In der varianzanalytischen Auswertung der Anzahl der Totimplantate (Tabelle 13) lag die Differenz zwischen der Kontrolle und der Blankophor P-Gruppe an der Signifik nzgrenze (p = 0,0564). Wertete man das Verhältnis der Totimplantate zu der Gesamtimplantaten varianzanalytisch aus (Tabelle 1%), so war der Unterschied zwisch der Kontrolle und der Blankophor P-Gruppe statistisch signifikant (p = 0,044).

Die Auswertung der Totimplantate des 1. Experiments mit einer anderen biometrischen Methode, und zwar mittel des Häufigkeitsverteilungsvergleichs (Kolmogorov-Smirno Test), ergab in einzelnen Paarungswochen (Tabelle 15) oder in der gesamten, 8-wöchigen Versuchsdauer (Tabelle 16) keine statistischen Signifikanzen, wohl aber war de Unterschied zwischen der Kontrolle und der Blankophor P-Gruppe in der 3. Woche statistisch auffällig (p = 0,0924).

Im 2. Versuch, ebenfalls mit 5 g/kg KG p.o., wies die mit Blankophor P behandelte Gruppe wiederum in der 2. Paarungswoche - jedoch nicht in der 3. Woche - relativ hohe postimplantative Verluste auf verglichen mit der Kontrolle.

L T

Mittels Varianzanalysen (Tabellen 17 und 18) und Häufigkeitsverteilungsvergleiche (Tabellen 19 und 20) war der Effekt nicht zu sichern, er lag aber nahe der Signifikanzgrenze (p = 0,0879, Toelle 19).

Im 3. Versuch, bei Gabe von 1 g/kg und 5 g/kg KG p.o., unterschieden sich die postimplantativen Verluste der Kontrolle und der 1 g/kg-Gruppe nicht bedeutsam; die 5 g/kg-Gruppe wies in der 1. Paarungswoche von insgesamt 3 relativ hohe postimplantative Verluste auf im Vergleich zur Kontrolle

Die statistische Auswertung der Daten (Varianzanalysen, Tabellen 21 und 22 und Kolmogorov-Smirnov-Tests, Tabellen 23 und 24) ergab keine Signifikanzen.

Zusammenfassend ist festzustellen:

In allen 3 Experimenten fanden sich Hinweise, daß die Blankophor P-Behandlung der Männchen mit 5 g/kg KG p.o. – zwar nicht in völlig identischen Paarungswochen, aber doch in einer einheitlichen Phase der Spermatogenese, nämlich der postmeiotischen Phase – die postimplantativen Verluste steigerte. Die Effekte waren schwach und nur im 1. Versuch statistisch signifikant, im 2. Versuch waren sie fast signifikant.

Die Prüfung der Dosis 1 g/kg KG p.o., die im 3. Versuch über die kritischen, ersten 3 Paarungswochen zusätzlich durchgeführt wurde, erbrachte keinen Anhaltspunkt für einen Effekt dieser Dosis auf die postimplantativen Verlustev

3.2.3. Die in den 3 Experimenten ermittelten <u>praeimplantativen</u>

Verluste, ausgedrückt als Differenz zwischen der Anzahl
der Corpora lutea und der Anzahl der Implantationen, wurde
in den Tabellen 5, 7 und 9 zusammengestellt. Die durchschnittliche Zahl der Implantationen (indirektes Maß des
praeimplantativen Verlustes) ist ebenfalls aus diesen
Tabellen ersichtlich.

Die Ergebnisse sprechen nicht für einen nachteiligen Einfluß von Blankophor P in Dosen bis 5 g/kg KG p.o.

Im Kolmogorov-Smirnov-Test zur Prüfung der Häufigkeitsverteilungen der praeimplantativen Verluste (Corpora
lutea minus Implantationen, (Tabellen 25 und 26 = 1.

Versuch, Tabellen 27 und 28 = 2. Versuch, Tabellen
29 und 30 = 3. Versuch) sowie der Implantationszahlen
(Tabellen 31 und 32 = 1. Versuch, Tabellen 33 und 34
= 2. Versuch, Tabellen 35 und 36 = 3. Versuch) ergaben
sich in den einzelnen Paarungswochen und auch während des
gesamten Versuchs keine signifikanten Unterschiede zwischen
der Kontrolle und den Blankophor P-Gruppen.

Bei der Varianzanalyse der Implantatzahlen der Weibchen zeigte sich ebenfalls kein signifikanter Unterschied zwischen den Versuchsgruppen (Tabelle 37 = 1. Versuch, Tabelle 38 = 2. Versuch, Tabelle 39 = 3. Versuch).

Die Varianzanalysen der Implantatzahlen ergaben lediglich einen signifikanten Zeiteinfluß in den ersten beiden Experimenten, die jeweils 8 Wochen umfaßten. D.h. die Implantations zahlen änderten sich im Verlaufe des Versuchs signifikant, de aber zwischen den unbehandelten und den behandelten Gruppen kein Unterschied bestand, war kein Präparateinfluß anzunehmen

# Zusammenfassend ist festzustellen:

3 unabhängige Experimente ergaben keinen Hinweis auf einen steigernden Einfluß von Blankophor P in Dosen bis 5 g/kg KG p.o. auf die praeimplantativen Verluste im Dominant-Letal-Test.

### 4. BEURTEILUNG

Das wichtigste Beurteilungskriterium für eine induzierte mutagene Wirkung ist in diesem Testmodell der postimplantative Verlust (1). Da sich in allen 3 Experimenten mit Blankophor P Hinweise dafür ergaben, daß nach akuter oraler Verabreichung von 5 g/kg KG an männliche Mäuse in bestimmten Paarungswochen die postimplantativen Verluste im Vergleich zur Kontrolle zugenommen hatten, muß man eine mutagene Wirkung von Blankophor P, 5 g/kg KG p.o., annehmen. Die Effekte waren zwar nur in einem Experiment statistisch signifikant und in einem anderen Experiment fast signifikant, aber die gleichartigen, wenn auch geringen Effekte sprechen für einen Substanzeffekt.

Die Effekte traten in den verschiedenen Experimenten nicht exakt in den gleichen Paarungswochen auf, was aufgrund der biologischen Gründlagen und des methodischen Ansatzes des Dominant-Letal-Test nicht unbedingt zu fordern ist, wichtig war jedoch, daß die Befunde in gleichen Spermatogenesestadien induziert wurden. Es handelt sich hierbei um postmeiotische Stadien (4), d.h. Spermatiden und Spermatozoen, die sich als die empfindlichsten Stadien für mutagene Einflüsse erwiesen haben (5).

Eine zusätzlich durchgeführte Prüfung von 1 g Blankophor P prockg KG p.o. während der kritischen postmeiotischen Phase (\* - 3. Paarungswoche nach Applikation) ergab keinen Hinweis auf mutagene Effekte.

Die Parameter Befruchtungsquote und praeimplantativer Verlust, die allerdings für die Beurteilung einer mutagenen Wirkung weniger bedeutsam sind als der postimplantative Verlust, ließen in keiner Untersuchung mit Blankophor P in Dosen bis 5 g/kg KG p.o. auf nachteilige Substanzeffekte schließen.

Abschließend ist festzustellen, daß Dominant-Letal-Untersuchungen mit Blankophor P an männlichen Mäusen Anhaltspunkte für eine mutagene Wirkung der akuten oralen Dosis von 5 g/kg KG ergeben haben. Die akute Dosis von 1 g/kg KG per os war in der entsprechenden Versuchsanordnung eine no-effect-Dosis.

Dr. E.

BAYER AG INSTITUT FÜR TOXIKOLOGIE Wuppertal-Elberfeld,

Bericht Nr.: 6721

Exemplar Nr.: 6

CONTAINS NO CEL

DOMINANT-LETAL-TEST AN MÄNNLICHEN MÄUSEN ZUR PRÜFUNG AUF MUTAGENE WIRKUNG VON BLANKOPHOR P FABRIKWARE IM VERGLEICH ZU BLANKCPHOR P GEREINIGTE WARE

Dr. L. Machemer

Die Ergebnisse dieser Untersuchung dürfen nur mit Einverständn der BAYER AG, Institut für Toxikologie, verwendet werden. Eine Vervielfältigung dieses Berichts - auch auszugsweise - ist nic erlaust.

### ZUSAMENFASSUNG

Blankophor P wurde im Vergleich zu einer Kontrolle in zwei Prüfmustern, Fabrikware und gereinigte Ware, im Dominant-Letal-Test nach einmaliger oraler Behandlung männlicher Mäuse in der adaequaten Dosis bezogen auf Farbsäure, 5000 bzw. 4734 mg/kg Körpergewicht, auf mutagene Wirkungen geprüft. Es sollte damit geprüft werden, ob Blankophor P mutagen wirkt, und ob eine mögliche Mutagenität auf evtl. Verunreinigungen in der Fabrik-ware zurückgeführt werden kann.

50 männliche Mäuse pro Gruppe und 50 weibliche Mäuse pro Gruppe pro Paarungspericde (insgesamt 5 zu je 4 Tagen) wurden verwendet

Blankopher P führte in beiden Prüfmustern in der untersuchten Dosis zu einer leichten, ca. 30 Minuten nach Applikation anhaltenden Somnolenz der Tiere, jedoch nicht zu bedeutenderen Schädigungssymptomen oder gar Todesfällen.

Der postimplantative Verlust zeigte in beiden Prüfmustern in der 4. Paarungsperiode eine geringe Erhöhung im Vergleich zur Kontrolle, die aber zu gering war, um eine mutagene Wirkung definitiv festzustellen.

Hinsichtlich des Befruchtungsergebnisses, der Implantationsquot (indirektes Maß des Praeimplantationsverlusts und der Quote der lebender. Implantate fanden sich mit der gereinigten Ware nicht aber mit der Fabrikware in den ersten 3 Paarungsperioden gering Verschlechterungen im Vergleich zur Kontrolle, die aber ebenfal zu gering waren, um einen Unterschied zwischen den Prüfmustern schlüssig festzustellen.

Somit kann gesagt werden: Die beiden Prüfmuster unterschieden sich nicht im Dominant-Letal-Test, insbesondere wenn man den postimplantativen Verlust betrachtete. Die Befunde waren nicht schlüssig im Sinne eines mutagenen Effektes zu interpretieren, sondern lediglich als geringer Hinweis darauf. Dem Ergebnis kom insofern keine praktische Bedeutung zu, da eine extrem hohe Dos gegeben wurde, die bereits toxische Symptome (Somnolenz) hervor rief. Da die Problematik von no-effect-Dosen bei mutagenen Effekten sehr schwierig ist, sollte man aus Sicherheitsgründen jede Exposition beim Herstellungs- und Verarbeitungsprozess vermeiden.

### 1. EINLEITUNG

Der vorliegende Bericht handelt von Untersuchungen, in denen Blankopher P in zwei Prüfmustern, Fabrikware und gereinigte Ware, im Dominant-Letal-Test an männlichen Mäusen geprüft wurde um zu prüfen, ob die Fabrikware möglicherweise mutagene Verunreinigungen enthält. Die Dosen wurden so gewählt, daß beide Behandlungsgruppen mit der gleichen Dosis, bezogen auf die reine, wasserfreie Farbsäure, behandelt wurden.

Der für die Untersuchung verwendete NMRI-Mäusestamm reagiert nach unseren Erfahrungen empfindlich auf bekannte chemische Mutagene.

Die Untersuchungen erfolgten nach einer verbesserten Methode, die von der Arbeitsgruppe "Dominante Letalmutationen" des ad hoc Ausschuss Chemogenetik des Bundesministeriums für Forschung und Technologie erarbeitet wurde (3). Diese Methode sieht u.a. einen 4-Tage-Paarungsrhythmus und einen Paarungsmodus 1:1 vor.

Die Untersuchungen erstreckten sich über 5 Paarungsperioden zu je 4 Tagen unmittelbar nach der Applikation, da dies die empfindlichste Periode der Gametogenese (postmeiotische Stadien) für mutagene Einflüsse ist.

### 2. METHODEN

### 2.1. Substanzen

- a) Blankophor P, Na-Salz, Fabrikware, Partie 613/17. Gehalt an reiner, wasserfreier Farbsäure: 80,0%
- b) Blankophor P, saures Na-Salz, gereinigte Ware aus Partie 613/17.

Reinigung durch Lösen in Wasser, Fällung mit Salzsäure in Gegenwart von Kochsalz bei 70°C, Absaugen nach Ab-kühlung und Trocknen bei 50°C im Trockenschrank. Gehalt an reiner, wasserfreier Farbsäure: 84,5%

### 2.2. Tiere und Haltungsbedingungen

Mäuse des Stammes NMRI. Züchter und Lieferant S. Ivanovas GmbH, Kisslegg/Allgäu. Das Gewicht der Männchen betrug zu Versuchsbeginn 33 - 37 g, das Gewicht der Weibchen lag zwischen 28 und 33 g. Das Alter der Tiere war ca. 11 Wochen. 50 männliche und 248-250 weibliche Mäuse pro Gruppe.

Die Zuordnung der Tiere auf die Gruppe erfolgte nach einem Randomisierungsplan.

Haltung in Makrolonkäfigen, Typ I:

- a) während der Verpaarung je ein Männchen mit einem Weibcher
- b) während der Gestation Einzelhaltung der Weibchen.

Standardisierte Haltungsbedingungen bei täglich 12-stündiger elektrischer Beleuchtung, 24 - 26°C Raumtemperatur und ca. 60% durchschnittlicher relativer Luftfeuchtigkeit.

Futter (Altromin®, pelletiert) und Leitungswasser ad libitum

### 2.3. Verabreichung der Substanz

Alle Weibchen im Versuch blieben unbehandelt.

Die Männchen der Blankophor P-Gruppen erhielten einmalig per os mit der Schlundsonde 5000 mg (Fabrikware) bzw. 4734 : (gereinigte Ware) pro kg Körpergewicht, 10%ig bzw. 9,468%ig in einer 2%igen wässrigen Cremophor EL-Emulsion (Applikation volumen 50 ml/kg Körpergewicht). Die Männchen der Kontrollgruppe bekamen das entsprechende Volumen der 2%igen Cremophor EL-Emulsion.

### 2.4. Paarung

Beginnend am Tag der Applikation wurden mit den Böcken 5 Paarungsperioden von je 4 Tagen Dauer durchgeführt, wobei jedesmal ein neues, unbehandeltes Weibchen zu jedem Bock gesetzt wurde.

Die Männchen und Weibchen wurden in Dauerverpaarung gehalten.

### 2.5. Untersuchung der Meibchen

Ca. 14 Tage ab Mitte der Paarungsperioden (17. Tag) erfolgte die Uterusuntersuchung zur Ermittlung der prae- und postimplantativen Verluste, der Kriterien für die Beurteilung. Hierz wurden die Implantationen, sowie die lebenden und die toten Implantat. (Surme der Deziduomata = "leere" Implantationsstellen, der Resorptionen sowie der toten Embryonen) gezählt.

### 2.6. Statistik

Das Befruchtungsergebnis wurde mit einer multidimensionalen Analyse für kategoriale Daten nach KU und KULLBACK ausgewertst Die Anzahl der toten Implantate und aller Implantate (wurzeltransformiert) sowie das Verhältnis der Totimplantate zu den Gesamtimplantaten (winkeltransformiert) wurden mit der zweifaktoriellen Varianzanalyse geprüft. Für die allgemeinen Vergleiche wurden die Grenzdifferenzen nach dem TUMEY-Test angegeben.

Die Kontraste zwischen den Prüfgliedern (Versuchsgruppen), sowie die Enderungen in der Zeit wurden mit der Methode der orthogonalen Vergliiche untersucht. Der in den Tabellen 5, 6 und 17 bezeichnete Kontrast "1 1" ist der Kontrast Fabrikware gegen Kontrolle. Der Kontrast "11-2" ist der Kontrast Kontrolle + Fabrikware gegen gereinigte Ware.

Ferner wurden mit dem verteilungsfreien KOLMOGOROV-SMIRMOV-Test die Häufigkeitsverteilungen einzelner Parameter (tote Implantate, lebende Implantate, Gesamt-Implantate) in der Kontrolle und den anderen Versuchsgruppen verglichen.

### 3. ERGEBNISSE

Die Auflistung der Einzelergebnisse aller verpaarten Weibchen findet sich im Anhang 1-10 zu diesem Bericht.

### 3.1. Allgemeine Verträglichkeit für die männlichen Mäuse

Die mit Blankophor P, Fabrikware oder gereinigten Ware, behandelten Männchen waren bis etwa 30 Minuten nach der Applikation leicht somnolent, dann waren sie bis Versuchsende unauffällig.

### 3.2. Mortalität

Alle behandelten männlichen Mäuse und alle Kontrollmännchen überlebten bis zum regulären Versuchsende.

Von den unbehandelten Weibchen schieden in der 3. Paarungsperiode folgende Tiere aus: 6 des 661(Fabrikware) infolge
Exitus nach Krankheit, 6 des 6 25 (gereinigte Ware) infolge
Exitus nach Verletzung am Käfigdeckel sowie 6 des 5 104 (gereinigte Ware) infolge Exitus mit ungeklärter Ursache.

### 3.3. Dominant-Letal-Untersuchungen

Es wurden folgende Hauptparameter ermittelt:

<u>Befruchtungsquote</u>: Darunter ist folgender Frozentsatz zu verstehen

Anzahl der befruchteten Weibchen x 100
Anzahl der eingesetzten Weibchen

Postimplantativer Verlust: Er stellt das wichtigste Kriterit für die Beurteilung einer mutagenen Wirkung in diesem Testmodell dar. Er ergibt sich aus der

Summe der Deziduomata der resorbierten Embryonen und der toten Embryonen. Praeimplantativer Verlust: Er wurde indirekt abgeschätzt durch einen Vergleich der durchschnittlichen Implantationszahlen pro befruchtetes Weibchen in der Kontrolle und den behandelten Gruppen.

Da die Implantationen im Gegensatz zu den Corpora lutea exakt zu zählen sind, gelangt die indirekte Acschätzung der praeimplantativen Verluste anhand der Implantationszahlen zu schlüssigeren Aussagen als die direkte auf der Basis der Corpora lutea-Zählung.

3.3.1. Das Befruchtungsergebnis wurde in den Tabellen 1 und 5 angegeben. Daraus ist ersichtlich, daß die Behandlung der Männchen mit der Fabrikware (5000 mg/kg) keinen bedeutsamen Einfluß auf das Befruchtungsergebnis hatte.

Die Behandlung der Männchen mit der gereinigten Ware (4734 mg/kg) führte zu einem leicht reduzierten Befruchtungsergebn im Vergleich zur Kontrolle, vor allem in den ersten 3 Paarungsperioden.

Die Ergebnisse der biometrischen Analysen der Befruchtungsergebnisse, die in den Tabellen 5 und 6 zusammengestellt wurden, ergaben keinen durch die Behandlung bedingten signifikanten Unterschied zur Kontrolle für die Fabrikware und einen fast signifikanten Unterschied (P = 0.0645) für die gereinigte Ware.

3.3.2. Der postimplantative Verlust und die Raten der lebenden Implantate pro Weibchen wurde in den Tabellen 2 und 4 zusammengestellt.

Aus den Ergebnissen ist ersichtlich, daß beide Gruppen, Fabrikware als auch gereinigte Ware, in der 4. Paarungsperiode (Tage 13 bis 16 nach Applikation) einen im Vergleich zur Kontrolle geringfügig erhöhten postimplantativen Verlust aufwiesen. Die Raten der Totimplantate lagen jedoch im Bereich der Norm des Stammes.

Die lebenden Implantate beider Gruppen lagen in allen Paarungsperioden im Bereich der Norm und lassen keinen nachteiligen Substanzeinfluß erkennen. In der 4. Periode lagen die Raten der lebenden Implantate der Behandlungsgruppen höher als oder genau so hoch wie in der Kontrolle.

Die Varianzanalyse der Totimplantate der Weibchen (Tabelle 7) ergab für die Fabrikware keinen signifikanten Unterschied zur Kontrolle während des gesamten Versuchs oder während einzelner Perioden. Für die gereinigte Ware ergab sich während des gesamten Versuchs kein signifikanter Unterschied, aber im 4. Paarungsintervall fand sich eine statistisch auffällige Erhöhung (P = 0,0904).

Die Varianzanalyse des Verhältnisses tote Implantate/alle Implantate (Tabelle 8) ergab für beide Gruppen (Fabrikware und gereinigte Ware) weder während des gesamten Versuchs noch während einzelner Paarungsperioden einen signifikanten Unterschied.

Die Häufigkeitsverteilungsvergleiche der Totimplantate der Kontrolle und der Blankophor-Gruppen mit dem KOLMOGOROV-SMIRNOV Test (Fabrikware: Tabellen 9 und 10; gereinigte Ware: Tabellen 11 und 12) erbrachten weder während einzelner Paarungsperioden noch während des gesamten Versuchs signifikante Differenzen.

Die entsprechenden Häufigkeitsverteilungsvergleiche der lebende Implantate zwischen Kontrolle und Behandlungsgruppen (Fabrik-ware: Tabellen 13 und 14; gereinigte Ware: Tabellen 15 und 16) erbrachte eine signifikant höhere Rate für die Fabrikware in der 3. Periode (P = 0,0009), sowie fast eine signifikant höhere Rate der Fabrikware während des gesamten Versuchs (P = 0,0522) und eine signifikant niedrigere Rate für die gereinigte Ware während des gesamten Versuchs (P = 0,0222), was vor allem auf die Unterschiede in den ersten 3 Paarungsperioden zurückging.

Hinsichtlich des postimplantativen Verlusts und der Raten der lebenden Implantate läßt sich abschließend feststellen, daß statistisch signifikante oder auffällige Unterschiede bestanden. Die tatsächlichen Unterschiede zwischen Kontrolle und Behandlungsgruppen spielten sich im Rahmen der biologischen Variabilität ab und waren so gering, daß sie kaum als Grundlage zur definitiven Feststellung eines mutagenen Effektes dienen können.

3.3.3. Die Raten der Implantationen pro Weibchen sind in den Tabelle 2 und 4 enthalten.

Daraus geht hervor, daß sich die Implantationszahlen zwischen Kontrolle und Fabrikware und damit die praeimplantativen Verluste nicht bedeutsam unterschieden.

Zwischen Kontrolle und gereinigter Mare zeigten sich geringfügige Unterschiede in den ersten 5 Paarungsperioden, da die Blankophor-Gruppe was niedrigere Werte als die Kontrolle aufwies, dies könnte auf einen leicht erhöhten Praeimplantationsverlust beruhen. Doch ist dies fraglich, da die Ergebnisse im Rahmen der Norm liegen.

Die Varianzanylse (Tabelle 17) ergab eine fast signifikante Abnahme der Implantationen bei der gereinigten Ware während der gesamten Versuchsdauer (P = 0.0536) und während des 5. Faarungsintervalls (P = 0.0013). Die Fabrikware war in dieser Analyse unauffällig.

Die Häufigkeitsverteilungsvergleiche der Implantate mit dem KOLMCGOROV-SMIRNOV-Test in Kontrolle und Blankophor-Gruppen ergab für die gereinigte Ware keinerlei Signifikanzen und für die Fabrikware eine statistische Signifikanz im 3. Paarungsintervall (P = 0,0017), allerdings war die Implantationsquote der Blankophor-Gruppe höher als in der Kontrolle und drückte somit keinen nachteiligen Effekt aus (Tabellen 18-21).

Es läßt sich somit hinsichtlich der Implantationsquote und somit für den Praeimplantationsverlust sagen, daß allenfalls die gereinigte Ware in den ersten 3 Perioden einen geringen nachteiligen Effekt gehabt haben könnte. Doch ist dies schwer schlüssig zu sagen, da die Differenzen zur Kontrolle im Rahmen der Norm lagen.

### 4. BEURTEILUNG

Zwei Fragen waren von Interesse:

- 1) Besitzt Blankophor P eine mutagene Potenz?
- 2) Bestehen zwischen der Fabrikware und der gereinigten Ware Unterschiede in der Wirkung, die möglicherweise auf mutagene Verunreinigungen der Fabrikware zurückgeführt werden können?

Was die erste Frage betrifft, so könnte man die bei beiden Prüfmustern beobachtete geringfügige Erhöhung der Totimplantatenrate in der 4. Paarungsperiode, die aber nur für die gereinigte Ware in den statistischen Berechnungen auffällig war, als Hinweis ansehen. Die Unterschiede waren aber sehr gering und traten im Rahmen der normalen Schwankungsbreite des Parameters auf, so daß die Frage nicht definitiv mit ja zu beantworten ist. Auffällig ist allerdings, daß beide Prüfmuster in der 4. Periode diese Erhöhung zeigten und scmit ein zeitlich übereinstimmendes Ergebnis vorlag.

Beim Praeimplantationsverlust fanden sich nur für die gereinigte Ware in den ersten 3 Paarungsperioden geringe Unterschiede zur Kontrolle, die aber ebenfalls zu gering waren, um klare Aussagen zu treffen. Dieser Parameter ist zudem für die Beurteilung einer mutagenen Potenz weniger beweiskräftig als der Postimplantations verlust (Totimplantate).

Was die zweite Frage betrifft, so kann man feststellen, daß kein substantieller Unterschied zwischen Fabrikware und gereinigter Ware festzustellen war. Zwar ließ die gereinigte Ware in den ersten 3 Paarungsperioden im Befruchtungsergebnis, in der Implantationsquote und als Folge davon auch in der Quote der lebenden Implantate, geringe Unterschiede zur Kontrolle erkennen, was bei der Fabrikware nicht der Fall war. Das Ausmaß des Effektes war aber gering, und die Befunde lagen im Schwankungsbereich der Morm, so daß man daraus keinen Unterschied zwischen den Prüf-

mustern herauslesen sollte. In jedem Fall aber wäre aufgrund der Befunde keine Interpretation möglich, die die Hypothese möglicher mutagener Verunreinigungen in der Fabrikware stützen würde. Denn in diesem Fall hätte die Fabrikware schlechter abschneiden müssen.

Betrachtet man den wichtigen Parameter in diesem Testmodell, den postimplantativen Verlust, so verhielten sich die Fabrikware und die gereinigte Ware völlig entsprechend.

Zusammenfassend kann man somit sagen, daß Fabrikware und gereinigte Ware des Blankophor P sich in ihrer Wirkung im Dominant-Letal-Test an männlichen Mäusen bei Verabreichung der gleichen Dosis, bezogen auf die reine, wasserfreie Farbsäure, nicht unterschieden. Die Befunde waren nicht schlüssig im Sinne einer mutagenen Wirkung zu interpretieren, sondern lediglich als geringer Hinweis darauf. Dem Ergebnis kommt insofern keine praktische Bedeutung zu, da eine extrem hohe Dosis gegeben wurde, die bereits toxische Symptome (Somnolenz) hervorrief. Da die Problematik von no-effect-Dosen bei mutagene Effekten sehr schwierig ist, sollte man aus Sicherheitsgründen jede Exposition beim Herstellungs- und Verarbeitungsprozess vermeiden.

Date: July 13,1995 Responsible:

Dr. H. Lehn

## 2. Summary

0

Blankophor P, sodium salt was evaluated for mutagenic potential in the dominant lethal test with male mice, each treated with a single oral dose of the test substance at a level of 2500 mg/kg and 5000 mg/kg body weight, respectively.

The doses tested were well tolerated and  $\operatorname{did}$  not cause any symptoms of toxicity nor mortality.

The fertility of the mice was not affected by the tested doses.

No treatment-related differences were seen between the Blankophor P, sodium salt-dosed groups and the control group with respect to those parameters of importance for an assessment of a mutagenic effect (dead implants, viable implants, total implants, pre-implantation loss).

The dominant lethal test on the male mouse provided no indication of Blankophor P, sodium salt having a mutagenic effect at the acute oral doses of 2500 mg/kg and 5000 mg/kg body weight.

The test followed the recommendations of the Ad Hoc Committee Chemogenetics (2), and was performed at the Carcinogenicity and Genotoxicity Unit of Toxicology, BAYER AG, Friedrich-Ebert-Straße 217-333, D-42096 Wuppertal, F.R.G.

Study initiation date: March 8, 1995
Study start date: March 13, 1995
Study termination date: May 12, 1995

Study completion date : report date (see front page)

The records are filed in the Fachbereich's archive.

A

In addition, positive controls are performed at regular intervals. The results of these experiments are reported separately

## 4.2 Animals and Husbandry

Mice, strain Bor:NMRI (SPF Han), bred and supplied by Harlan Winkelmann GmbH, Borchen, were used. The males' weight at start of test was 36-46 g. At the day of arrival the females weight was 26 to 34 g. According to these weights, the mice were about 6 to 12 weeks old.

The breed's state of health is regularly spot; checked for the main specific pathogens. The relevant documentation is filed in the Central Office for Laboratory Animals, BAYER AG, Wuppertal.

On the respective day of arrival, the animals' states of health were appraised, and they were acclimatized to the accommodation for a period of at least one week in Macrolon type II (00) and type III (90) cages. Only healthy animals without symptoms were used in the study.

The animals in this study were kept in Animal room no. 446, Building 514.

The animals were kept in Makrolon cages (with cage marks) on soft wood granules type S 8/15 (J. Rettenmaier & Söhne, Füllstoff-Fabriken, 73494 Ellwangen-Holzmühle) as follows:

- a) during mating 1 male and 1 female (type II cages)
- b) after mating females caged singly (type I cages).

The wood granules were spot-checked at regular intervals for contaminants. The relevant documentation is filed at the Central Office for Laboratory Animals, BAYER AG, Wuppertal.

Husbandry was standardized, with twelve hours of electrical lighting daily (6.00 hours to 18.00 hours, about 500 lux), 23\frac{1}{2}0.5°C room temperature, and 45-55% mean relative humidity. EP IT Elb. 2 (engineering department) gives the following settings for the animal room: 22\frac{1}{2}1.5°C, 40% to 70% humidity, and air change about ten times per hour.

The selection of the Blankophor P, sodium salt doses was based on a pilot test, in which five males were orally administered 5000 mg/kg Blankophor P, sodium salt. No symptoms were observed no animal died. Based on these results, 2500 and 5000 mg/kg Blankophor P, sodium salt were chosen for this test.

The males were allocated to the test groups by a random plan produced by the Institute of Biometrics, BAYER AG, Wuppertal. In the control and in the 2500 mg/kg Blankophor group 50 males were used, whereas in the 5000 mg/kg group 60 males were randomized. 10 males in this group were included as replacement if males would die during the conduct of the test. 50 males per group were used for assessment. In the 5000 mg/kg group those 50 males with the lowest random numbers were included in the assessment.

### 4.4 Mating

8

Starting with the day of administration, the males were mated for twelve periods each lasting four days; a new untreated virginal female being caged with each male at the beginning of each period. During 40 days, theoretically all the germ cell stages present in the testicles at the time of treatment could be used for insemination and fertilization of eggs. The males were mated continuously with females. No check was made for vaginal plug.

#### 4.5 Evaluation Procedure

Approximately fourteen days after the relevant mating period, the evaluation took place to assess for pre- and post-implantation losses. After sacrifice of the females, Caesarean section was performed. Uteri were spread out and the relevant parameters were examined. For this purpose, the total number of implantations, the number of living and dead implants as well as the number of corpora lutea was established. The number of dead implantations was established by counting the deciduomata ("empty" implantation sites), and dead implants.

4.9 Study Guidelines

The study was performed according at least to the following quidelines:

()

EEC Directive 87/302/EEC Ammalian In vivo - Dominant Lethal Test

OECD Guidelines for Testing of Chemicals
"Genetic Toxicology: Rodent Dominant Lethal Test"
Adopted: 4 April 84, No. 478

New and Revised Health Effects Test Guidelines October 1984. (U.S.) Environmental Protection Agency Washington, DC (PB 84-233295).

HG - Chrômo - Dom Lethal, October 1983

# b) Pre-implantation Loss:

This can be established in two ways:

- I directly from the difference between corpora lutea and total number of implantations.
- II indirectly derived from a comparison of the mean implantation counts per fertilized female in treatment and control groups.

As the implantations, unlike the corpora luter, can be counted exactly, indirect derivation of pre-implantation losses from the implantation count therefore provides more conclusive information than the direct method based on corpora lutea count, which nevertheless represents an additional cross-check.

 $\bigcirc$ 

c) Post-implantation Loss:

This represents the most important criterion for evaluating mutagenic effect in this test model. It is the result of adding:

deziduomata dead implantations

# 5.3.1 Fertilization Rates

The fertilization rates for the test with Blankophor P, sodium salt are shown in Table 1. As this table indicates, Blankophor P, sodium salt had no effect on the treated males' fertilization rates.

# 5.3.2 Previmplantation Losses

The pre-implantation losses, based on the implantation rates and corpora lutea per fertilized female, are compiled in Table 2. The data in this table show that Blankophor P, sodium salt had no effect on the pre-implantation losses.

The frequency distribution comparisons by the Kolmogorov-Smirnov test, in respect to total implants and pre-implantation losses based on the corpora lutea, did not detect any significant differences, neither for single periods nor for the total test.

#### 6. Conclusion

Blankophor P, sodium salt did not result in an effect on the animals' general behavior in the dominant lethal test after acute oral treatment of male mice with 2500 and 5000 mg/kg body weight. The treated mice did not show symptoms of acute toxicity. Their fertility remained unchanged. There were no treatment induced mortalities.

Statistical evaluation of the parameters relevant for assessment (dead and live implants, pre-implantation losses, total implants) did not detect any statistically significant variation. No effects were observed which might be interpreted as an adverse effect of Blankophor P, sodium salt.

There was, therefore, no indication of a mutagenic effect of Blankophor P, sodium salt at the acute oral doses of 2500 and 5000 mg/kg body weight in the dominant lethal test on the male mouse.
